[Document name] SPECIFICATION

[Title of the invention] Game system and game information storage medium used for same

[Claims]

[Claim 1]

A game system having in a related fashion, to a game apparatus having game program storage means storing a game program and processing means for executing the game program, display means to display an image based on a result of processing by the processing means, comprising:

a housing to be held by a player; and

change-state detecting means provided related to said housing and for detecting at least one of an amount and a direction of a change applied to said housing, wherein

said game program storage means stores

game space data including image data to display a space for game play;

a display control program to cause said display means to display a game space based on the game space data; and

a simulation program for simulating based on an output of said change-state detecting means such that a state of the game space is changed related to at least one of a change amount and a change direction applied to said housing.

[Claim 2]

A game system according to claim 1, wherein said change-state detecting means is to detect, as a change amount and direction, at least one of an amount and a direction of a tilt applied to said housing, and

said simulation program simulating related to the at least one of an amount and a direction of a tilt applied to said housing such that the game space is put into a tilt state.

[Claim 3]

A game system according to claim 1, wherein said change-state detecting means detects, as a change amount and direction, at least one of an amount and a direction of a movement applied to said housing, and

said simulation program simulating related to the at least one of an amount and a direction of a movement applied to said housing such that the game space is put into a tilt state.

[Claim 4]

A game system according to claim 1, wherein said change-state detecting means detects, as a change amount and direction, at least one of an amount and a direction of an impact applied to said housing, and

said simulation program simulating related to the at least one of an amount and a direction of an impact applied to said housing such that the game space is put into a tilt state.

[Claim 5]

A game system according to any of claims 1 to 4, wherein said change-state detecting means is for detecting both of an amount and a direction of a change applied to said housing, and

said simulation program simulating related to the both of an amount and a direction of an impact applied to said housing such that the game space is put into a tilt state.

[Claim 6]

A game system according to claim 1, wherein said housing is a housing of said game apparatus, and

said game apparatus being a portable game apparatus having said display means

provided integral on one main surface of said housing.

[Claim 7]

A game system according to claim 6, wherein said game program storage means is accommodated in a cartridge and detachably loaded in said housing of said portable game apparatus, and

said change-state detecting means detecting at least one of an amount and a direction of a change applied to said housing of said portable game apparatus when accommodated in said cartridge and said cartridge is loaded in said housing of said portable game apparatus.

[Claim 8]

A game system according to claim 7, wherein said change-state detecting means is for detecting an operation as a tool due to a change state applied to said housing of said portable game apparatus,

said game program storage means including a character data storage section to display a moving character movable on the game space,

the game space data being image data to provide display associating a tool having a function of controlling a movement of the moving character displayed on the game space, and

said game program storage means including a character control program to read out a moving character stored in said character data storage section and make processing related to at least one of a change amount and a change direction applied to said housing based on an output of said change-state detecting means such that a display state of the moving character is under control of the tool.

[Claim 9]

A game system according to claim 1, wherein said game program storage means

includes a character data storage section to display a moving character movable on the game space, and

said game program storage means including character control program to read out a moving character stored in said character data storage section and make control related to at least one of a change amount and a change direction applied to said housing based on an output of said change-state detecting means such that a display state of the moving character changes.

[Claim 10]

A game system according to claim 1, wherein said game program storage means further includes a non-player character data storage section to display a non-player character to make a first action on the game space according to a predetermined program irrespectively of an operation by the player, and

said simulation program controlling such that the non-player character makes a first action previously determined by a program when any of change states in amount and direction is not detected by said change-state detecting means, and such that the non-player character makes in addition to the first action a second action related to at least one of an amount and a direction of a change based on an output of said change-state detecting means when at least one of change states in amount and direction is detected by said change-state detecting means.

[Claim 11]

A game system according to claim 1, wherein said game program storage means includes a character data storage section to display a moving character movable on the game space,

the game space data including data to display a particular area defined such that, when the moving character moves on the game space, the moving character is different in

action from that in other area,

said simulation program controlling a display state of the moving character related to at least one of an amount and a direction of a change applied to said housing based on an output of said change-state detecting means, and display-controlling, when the moving character moves on the game space, the moving character is different in action from that in other area.

[Claim 12]

A game system according to claim 1, wherein the game space data includes space data to display a greater game space than a display area to be displayed by said display means,

the display control program being to display on said display means image data of a part of the game space existing in a range of the display area of the game space, and

said simulation program simulating a state of only the game space existing in the display area based on at least one of an amount and a direction of a change in an output of said change-state detecting means.

[Claim 13]

A game system according to claim 1, wherein said change-state detecting means detects as a change amount a moving amount of said housing and as a change direction a moving direction,

the game space data including space data to display a game space greater than a display area of said display means, and

the display control program displaying on said display means a space area of a part of a game space corresponding to the display area, and gradually moving the display area of the game space in the moving direction by an area corresponding to the moving amount according to a movement of said housing.

[Claim 14]

A game system according to claim 1, wherein said game apparatus has operating means to be operated by a player on one main surface of said housing, and
said simulation program changing a state of the game space in a manner of simulation based on a detection output of said change-state detecting means and an operating state of said operating means.

[Claim 15]

A game system according to claim 1, wherein said game program storing means includes a sound-generating program to generate sound corresponding to the game space state based on said simulating program.

[Claim 16]

16. A game information storage medium storing a game program and detachably loaded in a game system structured by operating means having display means in a related manner and including a housing to be held by a player, change-state detecting means provided related to the housing and for detecting at least one of an amount and a direction of a change applied to the housing, and processing means to display on the display means an image obtained by processing a program, storing:

game space data including image data to display a space for game play;

a display control program to cause said display means a game space based on the game space data; and

a simulation program to provide simulation based on an output of said change-state detecting means such that a state of the game space is changed related to at least one of an amount and a direction of a change applied to said housing.

[Claim 17]

A game information storage medium storing a game program and detachably

loaded in a portable game apparatus including a housing integrally having display means to be held by a player, and processing means to display on the display means an image obtained by processing a program, wherein

a change-state detecting means is provided related to the game information storage medium and for detecting at least one of an amount and a direction of a change applied to the game information storage medium, the game information storage medium storing:

game space data including image data to display a space for game play;

a display control program to cause said display means to display a game space based on the game space data; and

a simulation program to provide simulation based on an output of said change-state detecting means such that a state of the game space is changed related to at least one of an amount and a direction of a change applied to said housing.

[Claim 18]

A game information storage medium according to claim 17, wherein said change-state detecting means is for detecting both of an amount and a direction of a change applied to said housing, and

said simulation program simulating such that a state of the game space is changed related to the both of an amount and a direction of a change applied to said housing.

[Claim 19]

A game system structured at least by two game apparatuses, wherein

the two game apparatuses each have game program storage means to store a program, processing means to execute a game program, and a housing to be held by a player, and in a related fashion display means to display an image based on a result of processing by said processing means,

at least one of the two game apparatuses being provided related to said housing

and having change-state detecting means to detect at least one of an amount and a direction of a change applied to the housing,

data transmitting means further provided connected to the two game apparatuses and for transmitting mutually-related data to the game apparatus on the opposite side,

the respective of the game program storage means of the two game apparatuses storing the following:

game space data including image data to display a space for game play; and

display control programs to cause said display means to display a game space based on the game space data, wherein

said game program storage means of at least the other of said two game apparatuses further including a simulation program to provide simulation based on an output of said change-state detecting means of said one game apparatus transmitted through said data transmitting means such that a state of the game space of the other of said game apparatuses is changed related to at least one of an amount and a direction of a change applied to said housing of one of said game apparatuses.

[Claim 20]

A game system according to claim 19, wherein said change-state detecting means are respectively provided on said two game apparatuses, and

the respective of said game program storage means of said two game apparatuses storing a simulation program to provide simulation based on an output of said change-state detecting means of said one game apparatus such that a state of the game space of said the other game apparatus is changed related to at least one of an amount and a direction of a change applied to said housing of said one game apparatus.

[Claim 21]

A game system according to claim 19, wherein the game space data stored in said

game program storage means of said one game apparatus and the game space data stored in said game program storage means of said the other game apparatus are selected same game space data,

the simulation program of said one game apparatus changing a state of the game space of said one game apparatus correspondingly to a state of the other game space to be simulated by the game space control program, and

the simulation program of said other game apparatus changing a state of the game space of said the other game apparatus correspondingly to a state of one game space to be simulated by the game space control program.

[Detailed description of the invention]

[0001]

[Industrial field of utilization]

This invention relates to a game system and game information storage medium used for same. More particularly, the invention relates to a game system and game information storage medium used for same, which detects a change amount and direction of a tilt, movement or impact applied to a housing of a portable game apparatus or to a controller of a video game apparatus.

[0002]

[Prior art]

In operating the conventional portable game apparatus, a player manipulates the operation switch, such as a direction instructing key (joystick) or buttons while holding the video game machine's controller (controller housing) or portable game apparatus' housing by both hands. For example, if the player presses a direction instructing key at any one of up, down, left and right pressing points, a moving (player-controlled) character is moved in the pressed direction of up, down, left or right. If the action button

is operated, the moving character is changed in state of display, e.g. the moving character is caused in action, such as jump, as defined on the action button.

Also, in the conventional game apparatus or game software (game information storage medium), the player can operate the operation switch in order to change the motion of a moving (player-controlled) character acting as a player's other self on the screen. Consequently, it has been difficult for the player to change the game space (or background scene) freely through his or her manipulation.

[0003]

[Problem to be solved by the invention]

In the conventional game operation method, the player has been required to remember the way to operate a game according to the suggestion given in the game-software instruction manuals. Furthermore, the use of general-purpose operation switch has made it difficult to realize a change of the game space (or game scene) in a manner matched to an operation-switch manipulation feeling of the player, resulting in mismatch between operation feeling and screen-display state. Under such situations, the player possibly has encountered difficulty in concentrating on a game play before mastering the way to manipulate the game, losing his or her interest.

Meanwhile, with the conventional game apparatus or game software, the game space (or background scene) could not have been changed by player's operation, thus insufficient in game space variation and hence amusement.

[0004]

Therefore, it is a primary object of the invention to provide a game system and game information storage medium used for same which can change the state of a game space according to operation by a player.

Another object of the invention is to provide a game system and game information

storage medium used for same which can change the state of a game space through simple operation so that a player can concentrate on game play with enhanced enthusiasm without the necessity of skill on operation way.

Still another object of the invention is to provide a game system and game information storage medium used for same which can realize the change of a game scene matched to an operation feeling through the match between player's operation and game-space change.

Yet another object of the invention is to provide a game system and game information storage medium used for same which can change the state of a game space through the interaction with a plurality of portable game apparatuses to allow a plurality of players to cooperate or compete with thereby providing a variety of game-space change states, enhanced interest of game and virtual reality amusement.

[0005]

[Means for solving the problem]

A first invention (invention of claim 1) is a game system having in a related fashion, to a game apparatus having game program storage means storing a game program and processing means for executing the game program, display means to display an image based on a result of processing by the processing means. Provided are a housing to be held by a player and change-state detecting means. The change-state detecting means is provided related to the housing and detects at least one of an amount (e.g. tilt amount, movement amount, impact amount or the like) and a direction (e.g. tilt direction, movement direction, impact direction or the like) of a change applied to the housing. The game program storage means stores game space data, a display control program and a simulation program.

The game space data includes image data to display a space for game play. A

display control program causes the display means to display a game space based on the game space data. A simulation program simulates based on an output of the change-state detecting means such that a state of the game space is changed related to at least one of a change amount and a change direction applied to the housing.

[0006]

Here, game space means a world of a game that the game is possible to play, and is different by game kind or genre and presented to a player through a display screen. For example, for an action or roll-playing game having a moving (player-controlled) character to move therein, game space may be a background, a maze or other maps. For a battle game, it may be a ring (in addition to this, included is a space of audience seats and the above of ring). For a race game, it may be a space of a course for running and a periphery of the course. For a shooting game, a background scene such as a cosmic space for a background of a character (however, characters are not requisite, and a game space no character exists is to be contemplated). In a game using a tool, game space may be a scene to associate use of a tool.

Simulation refers to game control for analogously representing a change caused in the actual space in a form of a game-space state change, based on at least one of an amount and a direction of a tilt, movement or impact applied to the housing. Game control includes the case of simulation on a state change of the game space itself and the case of simulation of an indirect effect upon another object caused due to a change in state of the game space. The former is a case that simulation is made such that, when an impact is given to the housing, a land in the game space is transformed on an assumption that energy has been supplied to the game space. The latter is a case that simulation is made such that, when the housing is tilted, a ball existing on a maze plate rolls on an assumption that the maze plate as an example of a game space is tilted. Where simulating a state

change of a game space, it is possible to consider a case of varying a parameter such as of temperature rise in the game space, in addition to the case of causing a change of display including land transformation.

[0007]

A second invention (invention of claim 15) is a game information storage medium storing a game program and detachably loaded in a game system structured by operating means having display means in a related manner and including a housing to be held by a player, change-state detecting means provided related to the housing and for detecting at least one of an amount and a direction of a change applied to the housing, and processing means to display on the display means an image obtained by processing a program. The game information storage medium stores game space data, a display control program and a simulation program.

The game space data includes image data to display a space for game play. A display control program causes the display means a game space based on the game space data. A simulation program provides simulation based on an output of the change-state detecting means such that a state of the game space is changed related to at least one of an amount and a direction of a change applied to the housing.

[0008]

A third invention (invention of claim 16) is a game information storage medium storing a game program and detachably loaded in a portable game apparatus including a housing integrally having display means to be held by a player, and processing means to display on the display means an image obtained by processing a program, wherein a change-state detecting means is provided related to the game information storage medium and for detecting at least one of an amount and a direction of a change applied to a housing of the portable game apparatus.

The game information storage medium stores game space data, a display control program and a simulation program. The game space data includes image data to display a space for game play. A display control program causes the display means to display a game space based on the game space data. A simulation program provides simulation based on an output of the change-state detecting means such that a state of the game space is changed related to at least one of an amount and a direction of a change applied to the housing.

[0009]

A fourth invention (invention of claim 18) is a game system structured at least by two game apparatuses to be interacted with each other. The two game apparatuses each have game program storage means to store a program, processing means to execute a game program, and a housing to be held by a player, and in a related fashion display means to display an image based on a result of processing by the processing means. At least one of the two game apparatuses is provided related to the housing and having change-state detecting means to detect at least one of an amount and a direction of a change applied to the housing. The game system further having data transmitting means connected to the two game apparatuses and for transmitting mutually-related data to the game apparatus on the opposite side.

The respective of the game program storage means of the two game apparatuses store game space data and display control programs. The game space data includes image data to display a space for game play. The display control program to cause the display means to display a game space based on the game space data. The game program storage means of at least the other of the two game apparatuses further includes a simulation program to provide simulation based on an output of the change-state detecting means of the one game apparatus transmitted through the data transmitting means such that a state

of the game space of the other of the game apparatuses is changed related to at least one of an amount and a direction of a change applied to the housing of one of the game apparatuses.

[0010]

[Effect of the invention]

According to this invention, it is possible to obtain a game system and game information storage medium used for same that can change a state of a game space.

Also, according to the invention, a game system and game information storage medium used for same is to be obtained which can change the state of a game space through simple operation so that a player can concentrate on game play with enhanced enthusiasm without the necessity of skill on operation ways.

Also, according to the invention, a game system and game information storage medium used for same is to be obtained which can realize the change of a game scene matched to an operation feeling through the match between player's operation and game-space change.

Further, according to the invention, a game system and game information storage medium used for same is to be obtained which can change the state of a game space through the interaction with a plurality of portable game apparatuses to allow a plurality of players to cooperate or compete with thereby providing a variety of game-space change states, enhanced interest of game and virtual reality amusement.

[0011]

[Embodiments of the invention]

(First Embodiment)

With reference to Figure 1 to Figure 40, explanations will be made on a portable game apparatus according to a first embodiment of the present invention. Figure 1 is an

outside view showing a portable game apparatus (hereinafter, referred merely to as "game apparatus"). The game apparatus includes an apparatus main body 10 and a game cartridge (hereinafter referred merely to as "cartridge") 30 to be unloadably loaded on the game apparatus main body 10. The cartridge 30, when loaded on the game apparatus main body 10, is put in electrical connection to the game machine main body. The game apparatus main body 10 is provided with a housing 11. The housing 11 includes therein a board having circuits configured as shown in Figure 3, hereinafter described. The housing 11 has, on one main surface, a LCD 12 and operation keys 13a – 13e and, on the other surface, a hole (cartridge insertion hole) 14 formed to receive a cartridge 30. A connector 15 is provided on a side surface, to allow connection with a communication cable for communication, as required, with other portable game apparatuses.

[0012]

Figure 2 is an illustrative view showing a relationship between the game apparatus and XYZ axes thereon. In a state the portable game apparatus is positioned with the LCD 12 directed up and the operation switches positioned toward this, an X-axis is taken in a horizontal direction of the game apparatus (a plus direction taken rightward), an Y-axis is in a vertical direction (a plus direction taken depthwise), and a Z-axis is in a thickness direction (a plus direction taken upward).

[0013]

Figure 3 is a block diagram of the game apparatus. The game apparatus main body 10 incorporates a board 27 therein. The board 27 is mounted with a CPU 21. The CPU 21 is connected with a LCD driver 22, an operation key 13, a sound generator circuit 23, a communication interface 24, a display RAM 156 and a work RAM 26. The sound generator circuit 23 is connected with a speaker 16. The communication interface 24 is to be connected to another game apparatus 40 through a connector 15 and communication

cable 50. Note that, although the communication method with the other game apparatus 40 was shown by a method using the communication cable 50, it may use radio communication, handy phone or the like.

[0014]

The cartridge 30 incorporates a board 36. The board 36 is mounted with a program ROM 34 storing a game program and game data, hereinafter described with reference to Figure 16, and a backup RAM 35 storing a game data, hereinafter described with reference to Figure 19. In addition to these storage means, the cartridge 30 includes, as one example of detecting means for detecting tilt, movement and impact to the portable game apparatus main body, an XY-axis acceleration sensor 31 to detect accelerations in X-axis and Y-axis directions and a Z-axis contact switch 32 to detect an acceleration in a Z-axis direction. Also, the cartridge 30 includes a sensor interface 33 as an interface to the acceleration detecting means. Where using a triaxial acceleration sensor capable of detecting accelerations in all the X-axis, Y-axis and Z-axis directions, the Z-axis contact switch 32 will be unnecessary. Incidentally, the biaxial acceleration sensor (XY-axis acceleration sensor) is more inexpensive than that sensor. Because this embodiment does not require high accuracy of acceleration detection in the Z-axis direction, a Z-axis contact switch 32 is employed that is simple in structure and cheap in price. Also, where high accuracy is not required in the XY-axis direction, detecting means having a similar structure to the Z-axis contact switch may be used in detecting an acceleration in the XY-axis direction.

[0015]

The program ROM 34 is stored with a game program to be executed by a CPU 21. The work RAM 26 is stored with temporary data required to execute the game program. The backup RAM 35 is to store game data to be kept memorized even where a power to

the game apparatus be turned off. The display data obtained through executing the game program by the CPU 21 is stored in the display RAM 25, which can be displayed on the LCD 12 through a LCD driver 22. Similarly, the sound data obtained through executing the game program by the CPU 21 is delivered to the sound generator circuit 23 so that sound is generated as effected sound through the speaker 16. Operation switches 13 are for game operation. However, the operation key 13 is auxiliary one as far as the present embodiment is concerned. The player is allowed to operate for game play principally by tilting or moving or giving impact to the game apparatus. The tilt, movement and impact to the portable game apparatus during game operation are to be detected by the XY-axis acceleration sensor 31 and Z-axis contact switch 12. The CPU 21 can execute the game program by utilizing the output values of the acceleration detecting means.,

[0016]

For a game with using a plurality of game apparatuses, the data obtained through executing a game program by the CPU 21 is delivered to the communication interface 24 and then sent to another portable game apparatus 40 via the connector 15 and communication cable 50. Meanwhile, the game data of the other game apparatus 40 comes to the CPU 21 through the communication cable 50, connector 15 and communication interface 24.

[0017]

Figure 4 is a detailed block diagram of the sensor interface 33. The sensor interface 33 includes an X counter 331, a Y counter 332, a count stop circuit 333, latches 334 and 335, a decoder 336 and a general-purpose I/O port 337. The X counter 331 counts pulses of a clock signal Φ based on an XY-axis output of the acceleration sensor 31. The Y counter 332 counts pulses of the clock signal Φ based on a Y-axis output. The count stop circuit 333 sends a count stop signal to the X counter 331 in response to a fall

in an X-axis output of the XY-axis acceleration sensor 31, and a count stop signal to the Y counter 332 in response to a fall in the Y-axis output. The latches 334 and 335 hold respective values of the X counter 331 and the Y counter 332. The decoder 336 transmits a start/reset signal to the X counter 331, Y counter 332, latches 334 and 335. The general-purpose I/O port 337 is used to connect with an extension unit. The latches 334 and 335 also hold an output value of the Z-axis contact switch 32 ("0" or "1"). Specifically, a highest order bit of the latch 334, 335 is assigned to an output value of the Z-axis contact switch 32, while the remaining lower order bits are assigned to the values of the X counter and Y counter. The extension units connectable to the general-purpose I/O port 337 include a vibration unit which vibrates in relation to a game program providing a game with a realism feeling.

[0018]

Figure 5 is an illustrative view showing a principle that the sensor interface 33 measures a count value having a corresponding magnitude to an acceleration from an output of the acceleration sensor 31. The acceleration sensor 31 in this embodiment outputs a signal representative of an acceleration magnitude with a duty ratio changed with respect to one period of a waveform (period 1). It is shown in this case that the greater the ratio of a high level period (period 2 or period 3) within one period the greater an acceleration has been detected. Also, the acceleration sensor 31 outputs a magnitude of X-axis acceleration through its X-axis output and a magnitude of Y-axis acceleration through the Y-axis output.

[0019]

When a count start signal outputted from the decoder 336 becomes a low level, the X counter 331 detects a rise from low to high level in the X-axis output and then starts counting. Specifically, the X counter 331 inches up its count value each time a clock

signal Φ is given, and stops the counting in response to a count stop signal sent from the count stop circuit 333. In this manner, the X counter 331 counts on the clock signal Φ during a period (period 2) of between a rise of an X-axis output to a high level and a fall of same to a low level, immediately after the count start signal has become a low level. The Y counter 332, similarly, counts on the clock signal Φ during a period (period 3) of between a rise of the Y-axis output to a high level and a fall of same to a low level, immediately after the count start signal has become low level. In this manner, the X counter 331 holds a count value dependent upon a magnitude of an X-axial acceleration while the Y counter 332 holds a count value dependent upon a magnitude of a Y-axial acceleration. The values of the X counter 331 and Y counter 332 are held in the latch 334 and latch 335 so that the data of latches 334 and 335 can be read out by the CPU 21 through the data bus and utilized for a game program.

[0020]

The X counter 331 and the Y counter 332 each perform counting, for example, from "0" up to "31", wherein setting is made such that, with respect to a count value "15" as a reference (acceleration 0), - 2G (twice a gravity acceleration in a minus direction) is assigned by a count value "0" and 2G (twice the gravity acceleration in a plus direction) is by a count value "31". The CPU 21 reads in such a count value based on a game program wherein the count value "15" is read as "0", the count value "0" as "-15" and the count value "31" as "16". Accordingly, when the acceleration sensor 31 detects an acceleration in the minus direction, the CPU has a minus (-) reading value. When an acceleration in the plus direction is detected, the CPU has a plus (+) reading value.

[0021]

Figure 6 shows a structural of the contact switch 32. The contact switch 32 is structured by a spherical contact 321, contacts 322 and 323, and a box member 324 which

are formed of a conductor. Specifically, the spherical contact 321 is movably held almost at a center of a space defined within the member 324. (the box member 324 has, in its inner bottom, a depression (324a) at which the spherical contact 321 can be rested at almost the center). The box member 324 has, at above, sheet-formed contacts 322 and 323 having respective one ends formed with semicircular cut-outs (322a and 323a). The sheet contacts 322 and 323, at their other ends, are secured to a board 36 with the one ends opposed to each other. The box member 324 is fixedly held by the board 36 in a state of hung through the contact 322 and 323. With this structure, if the cartridge 30 is powerfully moved in the Z-axis direction (in a plus or minus direction), the spherical contact 321 shown in Figure 7 is moved in the Z-axis direction within the box member 324 and contacts with the contacts 322 and 323 simultaneously. Thus, the contact 322 and the contact 323 are conducted through the spherical contact 321, thereby detecting an acceleration input in the Z-axis direction. Based on a time for which the contact 322 and the contact 323 are in conduction, it is possible to detect a magnitude of acceleration in the Z-axis direction. Note that, when the cartridge 30 is moderately tilted, the spherical contact 321 moves in the box member 324 but does not short-circuit between the contacts 322 and 323, detecting no acceleration.

[0022]

Figure 8 shows an example of a game scene. In this game scene, there are displayed a ball 61 as one example of a player character, tortoises 62 as one example of an enemy character (non-player character; hereinafter abbreviated as "NPC"), and a wall 63 and hole 64 forming a maze. Because a game map is a virtual map that is broader than a display range on an LCD 12, LCD 12 can display only part of the game map so that scroll is made in accordance with the movement of the player character 61. Although three tortoises 62a - 62c are displayed as NPC on the LCD 12, there exist many of other

tortoises in the game map. Also, there exist on the game map such lands as floors, ice surfaces, and under waters.

[0023]

The ball 61 is changed in its moving amount or direction by player's operation, such as tilting of or applying movement or impact to the portable game apparatus. The shape is changed as required. Although the tortoise 62 is controlled of movement (moved by self-control) by the game program, it is moved or changed in shape where the player tilts, moves or gives impact to the portable game apparatus.

[0024]

Outlining this game, a player can manipulate the ball 61 on the game map with a maze formed by the walls 63, and smashes the tortoises 62a - 62c as an example of NPC. A tortoise if smashed will be vanished or erased away. If all the tortoises are successfully vanished out of the game map, game clear is reached. There exist some holes 64 on the game map. If the ball 61 is fallen into the hole 64, one mistake is counted or the game becomes over.

[0025]

Figure 9 to Figure 12 illustrate examples of game operation. Figure 9 illustrates a slide input in the X-axis or Y-axis direction. A movement (slide) in the X-axis direction is detected based upon an X-axis output of the XY-axis acceleration sensor 31, and a movement (slide) in the Y-axis direction is detected based on a Y-axis output of the XY-axis acceleration sensor 31 (acceleration is caused by movement in the X-axis or Y-axis direction). Figure 10 illustrates a tilt input about the X or Y axis. A tilt about the X-axis is detected based on a Y-axis output of the XY-axis acceleration sensor 31, and a tilt about the Y-axis is detected based upon an X-axis output of the XY-axis acceleration sensor 31 (a tilt if caused about the X-axis gives rise to acceleration in the Y-axis

direction due to gravity, and a tilt if caused about the Y-axis causes acceleration in the X-axis direction due to gravity). Figure 11 illustrates an impact input in the X-axis or Y-axis direction. The acceleration input in the X-axis direction is outputted at an X-axis output of the XY-axis acceleration sensor 31. In the case this output value is a constant value or greater, it is considered that there has been an impact input. Also, the acceleration input in the Y-axis direction is outputted at a Y-axis output of the XY-axis acceleration sensor 31. In the case this output value is a constant value or greater, it is considered that there has been an impact input. Figure 12 illustrates a movement input (or impact input) in the Z-axis direction. The movement (or impact) in the Z-axis direction is detected by the Z-axis contact switch 32.

[0026]

Figure 13 to Figure 15 illustrate an examples of a way to utilize the respective ones of game operation stated above. Figure 13 illustrates a way to utilize a slide input (as one example of a game scene in a game map select process hereinafter described with reference to Figure 30). In a case of displaying on the LCD 12 a part area of a virtual map broader than a display range of the LCD 12, the display area is scrolled by giving a slide input. Specifically, where providing a slide input in an X-axis plus direction, to be displayed is an area moved in the X-axis plus direction from the present display area. A slide input in the Y-axis direction is similarly processed to this. By thus processing a slide input, it is possible to provide a player with a feeling as if he or she peeps part of a vast world through the LCD 12. Incidentally, in this embodiment, such slide input alike this is merely utilized in a game map select process hereinafter described with reference to Figure 30, but not utilized in a game-map scroll process as a main game process. The way of processing to scroll a game map will be hereinafter described with reference to Figure 38 to Figure 40.

[0027]

Figure 14 illustrates a way to utilize a tilt input about an X or Y axis. Where there is a tilt input about the X-axis, display is made such that a game character in a game scene (player character 61 and NPC 62) is moving parallel in the Y-axis direction (where tilting in a plus direction about the X-axis, display is made such that the game character is moving parallel in a Y-axis minus direction). Also, where there is a tilt input about the Y-axis, display is made such that the game character in the game scene, player character 61 and NPC 62) is moving parallel in the X-axis direction (where tilting in a minus direction about the Y-axis, display is made such that the game character moves parallel in an X-axis minus direction). By thus processing a tilt input, it is possible to provide a player with a feeling as if a maze plate, as a game space, was tilted likewise the portable game apparatus and the game character was sliding (rolling) over the tilted maze plate. Incidentally, the game map includes lands, such as floor surface, ice surface and under-water, providing factors to vary a moving amount of the ball 61, so that an amount of movement is varied by a tilt input in a manner dependent upon a place where the game character is present. For example, the ball 61 is changed in magnitude of control in such a way that the movement amount is great on an ice surface easy to slide whereas the movement amount is small at under-water.

[0028]

Figure 15 shows a way to utilize impact input or Z-axis movement input. When an impact input is applied in the X-axis or Y-axis direction, a different process is performed from the tilt input process (game character movement due to tilting the maze plate). For example, waves are caused in a water surface as a game space. When an impact input is applied in the X-axis plus direction, waves are caused in the X-axis plus direction. When an impact input is applied in an X-axis minus direction, waves are caused in the X-axis

minus direction. This is true for an impact input in a Y-axis direction. Meanwhile, waves may be caused in a direction of a resultant vector of vector components, wherein an acceleration input in the X-axis direction is taken a vector component in the X-axis direction while an acceleration input in the Y-axis direction is a vector component in the Y-axis direction. The character is displayed as if it was carried away by the waves. The character may be put out of control while it is being carried by the waves. Also, when there is an input of movement in the Z-axis direction (or impact input), the ball 61 as one example of a player character is displayed varying to make a jump. By thus processing the movement input in the Z-axis direction, the maze plate as a game space moves in the Z-axis direction in a way similar to the game machine. This can provide the player with a feeling as if the game character on the maze plate was caused to jump. During the jump, the ball 61 will not move even if there is a tilt input. Also, when there is a movement input (or impact input) in the Z-axis direction, the tortoise 62 as NPC is turned upside down (a tortoise upside down returns to the normal position). The tortoise in an upside-down position is easy to slide, so that the movement process is made to give a greater tilt-input moving amount than that of the normal position.

[0029]

Figure 16 is a memory map of the program ROM 34. The program ROM 34 stores a game program and game data to be executed by the CPU 21. The program ROM 34 concretely includes an object character data memory area 34a, a map data memory area 34b, an acceleration-sensor output value conversion table memory area 34c and a game program memory area 34e. The object character data memory area 34a stores graphic data of the object characters. Because the object character has some poses (e.g. tortoise "normal position" and "upside-down position", etc.), for each character a plurality of ones of graphic data are stored for a plurality of poses. The map data memory area 34b stores

map data on a game map basis and game-map-select maps. The game-map select map is virtual map data to be displayed on the LCD 12 during a game map select process hereinafter described with reference to Figure 30.

[0030]

The acceleration-sensor output value conversion table memory area 34c stores conversion tables to convert output values of the XY-axis acceleration sensor 31 and Z-axis contact switch 32, for utilization in a game program. The conversion tables includes a game map select table, a player character moving table and an NPC moving table. Also, the player character moving table includes tables for in-air, on-floor, on-ice and under-water, which are to be selected depending upon a land coordinate where a player character is present. The NPC moving table includes tables for normal position and upside-down position. The tortoise as NPC assumes states of normal and backside-down positions, depending upon which a table is to be selected. The details of the tables will be hereinafter described with reference to Figure 20 to Figure 26.

[0031]

The game program memory area 34e stores various game programs to be executed by the CPU 21. Specifically, stored are a main program hereinafter described with reference to Figure 27, a 0G set program hereinafter described with reference to Figure 28, a neutral-position set program hereinafter described with reference to Figure 29, a game map select program hereinafter described with reference to Figure 30, a sensor output read program hereinafter described with reference to Figure 31, an object moving program hereinafter described with reference to Figure 32 to Figure 36, a collision program hereinafter described with reference to Figure 37, a screen scroll program hereinafter described with reference to Figure 40, an NPC self-controlled moving program and other programs.

[0032]

Figure 17 is a memory map of the work RAM 26. The work RAM 26 is to store temporary data for executing a game program by the CPU 21. Specifically, included are a neutral position data memory area 26a, an acceleration sensor memory area 26b, an impact input flag memory area 26c, a map select screen camera coordinate memory area 26e, a game map number memory area 26f and a character data memory area 26g.

[0033]

The neutral position data memory area 26a stores neutral position data (NPx, NPy, NPz) to be set in a neutral-position set process hereinafter described with reference to Figure 29. This is data concerning a reference tilt of the game apparatus for playing a game.

[0034]

The acceleration-sensor output value memory area 26b stores output values (INx, INy, INz) of the XY-axis acceleration sensor 31 and Z-axis contact switch 32 which are detected by the acceleration sensor 31 and contact switch 32 and to be read out through the sensor interface 33 in a sensor output read process of Figure 31. The impact input flag memory area 26c stores an impact input flag (FS) that assumes 1 when equal to or greater than a constant value is the magnitude of resultant vector of a vector component in the X-axis direction taken of an acceleration input in the X-axis direction and a vector component in the Y-axis direction taken of an acceleration input in the Y-axis direction. The determination of impact input is executed in a sensor output read process of Figure 31.

[0035]

The map select screen camera coordinate memory area 26e stores coordinates (Cx, Cy) at upper left corner of an LCD 12 display area in a game map select map which is to

be displayed in a game map select process hereinafter described with reference to Figure 30. The game map number memory area 26f stores corresponding number data (MN) to a game map having been selected by a player during a game map select process hereinafter described with reference to Figure 30.

[0036]

The character data memory area 26g stores, for each of the player characters and NPCs, moving acceleration data (Ax, Ay, Az), moving-acceleration change amount data (dAx, dAy, dAz), velocity data (Vx, Vy, Vz), coordinate data (X, Y, Z), last-time coordinate data (Px, Py, Pz), current position status (SP) and pose numbers (PN).

[0037]

The coordinate (Px, Py, Pz) in the last time is for returning to the last-time coordinate a player character or NPC when collided with a wall or the like. The current-position status data (SP) is data concerning a land at a coordinate where the player character is present. Based on this data, an acceleration-sensor output value conversion table (in-air, on-floor, on-ice, on-water) is to be selected. The pose number (PN) is data concerning a character state (pose) (e.g. tortoise normal and upside-down positions, etc.).

[0038]

Figure 18 is a memory map of the display RAM 25. The display RAM 25 is to temporarily store display data obtained through executing a game program by the CPU 21. The display RAM 25 has an object data memory area 25a, a scroll counter data memory area 25b and a map data memory area 25c. The object data memory area 25a stores data of the existing characters in the LCD 12 display area among all the characters to appear in a game. Specifically, stored area X-coordinates, Y-coordinates, character IDs, and pose numbers.

[0039]

The scroll counter data memory area 25b stores a relative coordinate of an upper left corner of the LCD 12 display area of the game. The map data memory area 25c stores game map data of the game map in an area to be displayed on the LCD 12.

[0040]

Figure 19 is a memory map of the backup RAM 35. The backup RAM 35 stores 0G position data (ZGx, ZGy) to be set in a 0G set process hereinafter described with reference to Figure 38. The 0G position data is to cope with not to have a sensor output value of 0 because of the error possessed by the XY-axis acceleration sensor even when the game apparatus is held horizontal. A sensor output value when the portable game apparatus is held horizontal is stored as 0G position data in the backup RAM 35, which in a game process is subtracted from a sensor output value.

[0041]

Figure 20 to Figure 26 illustrate in detail conversion tables stored in the acceleration-sensor output value conversion table memory area 34c of the program ROM 34. The tables store data, concerning utilization ways and correction of limiting a maximum values, etc., for utilizing, in game processing, sensor output values (INx, INy, INz) of the XY-axis acceleration sensor 31 and Z-axis contact switch 32 and impact input flag (FS). Specifically, stored is data concerning utilization ways, correction ratio, special correction conditions and special correction numbers. The tables are stored in plurality, including a game-map select process table, player-character moving table and an NPC moving table.

[0042]

The game map select processing table shown in Figure 20 is to be made reference to in a game map select process hereinafter described with reference to Figure 30. The output values (INx, INy) of the XY-axis acceleration sensor by this table are utilized for

calculating a camera coordinate (Cx, Cy) change amount. Incidentally, because the correction ratio is wise, the camera coordinate (Cx, Cy) will be moved twice the output value (INx, INy) of the XY-axis acceleration sensor 31. The output value (INz) of the Z-axis contact switch 32 is utilized for a map determining process. The impact input flag (FS) is not utilized.

[0043]

The player character moving table shown in Figure 21 to Figure 24 is made reference to in a tilt movement process to be executed at step 33, and in an impact movement process to be executed in step 33 in a player character moving process hereinafter described with reference to Figure 33. The player character moving table includes tables for in-air, on-floor, on-ice and under-water, Any one of the conversion tables is to be selected and referred to in accordance with a coordinate topology where the player character is present (current position status).

[0044]

In the player character moving table, the output value X (INx) of the XY-axis acceleration sensor 31 is utilized for calculating a change amount (dAx) of an X-movement acceleration of a player character while the output value Y (INy) is utilized for calculating a change amount (dAy) of an Y-movement acceleration. In the case the current position status is "in-air", the moving-acceleration change amount (dAx, dAy) is zero by referring to Figure 21. For the case of "on-floor", because the correction ratio if referred to Figure 22 is twice, twice the output value (INx, INy) of the XY-axis acceleration sensor 31 gives a change amount (dAx, dAy) of moving acceleration. Also, where the output value (INx, INy) of the XY-axis acceleration sensor is greater than 20 due to particular correction condition 1, the moving-acceleration change amount (dAx, dAy) is limited to "40". For "on-ice", by referring to Figure 23 three times the output

value (INx, INy) of the XY-axis acceleration sensor 31 gives a change amount (dAx, dAy) (greater moving amount "on-ice"). Meanwhile, where the output value (INx, INy) of the XY-axis acceleration sensor is greater than "20" due to particular correction condition 1, the moving-acceleration change amount (dAx, dAy) is limited to "60". For "under-water", by referring to Figure 24 a half of the output value (INx, INy) of the XY-axis acceleration sensor 31 gives a moving-acceleration change amount (dAx, dAy) (smaller moving amount "in water"). Also, where the output value (INx, INy) of the acceleration sensor 31 is greater than "10" due to particular correction condition 1, the change amount (dAx, dAy) is limited to "5".

[0045]

In the player character moving tables, the output value (INz) of the Z-axis contact switch 32 is utilized to calculate a change amount (dAz) of Z-movement acceleration. There is no special correction condition.

[0046]

In the player-character moving table, an impact input flag (FS) has an effect upon X and Y moving-acceleration change amounts (dAx, dAy). In the case the present position status is "in-air" and "under-water", the impact input flag (FS) is ignored by referring to Figure 21 and Figure 24. Where the present position status is "on-floor", with reference to Fig. 22 processing is made to multiply by 3 times the X and Y moving-acceleration change amounts (dAx, dAy). Where the current position status is "on-ice", with reference to Figure 23 processing is made to multiply by 5 times the X and Y moving-acceleration change amounts (dAx, dAy). In this manner, when there is an impact input, for "on-floor" and "on-ice" the X and Y moving-acceleration change amounts (dAx, dAy) are increased (moved at higher speed) as compared to the usual.

[0047]

The NPC moving tables of Figure 25 and Figure 26 are to be referred to in a tilt movement process in step 44 and impact moving process in step 45 of an NPC moving process hereinafter described with reference to Figure 34. The NPC moving tables includes tables for normal and upside-down positions. Any one of the two conversion tables is selected and referred to depending upon a pose (normal or upside-down) of a tortoise as NPC.

[0048]

In the NPC moving table, an output value X (INx) of the XY-axis acceleration sensor 31 is utilized to calculate a change amount (dAx) of an NPC X movement acceleration while an output value Y (INy) is utilized to calculate a change amount (dAy) of a Y movement acceleration. For the "normal position", because with reference to Fig. 25 the correction ratio is 1/2 times, 1/2 times an output value (INx, INy) of the XY-axis acceleration sensor 31 gives an X-and-Y moving-acceleration change amount (dAx, dAy). Also, where the output the values (INx, INy) of the XY-axis acceleration sensor 31 is smaller than 10 under special correction condition 1, the moving-acceleration change amount (dAx, dAy) is 0 (in the "normal position", with a small tilt the tortoise will brace its legs and not slide). Also, where the output (INx, INy) of the XY-axis acceleration sensor 31 is greater than 20 under special correction condition 2, the moving-acceleration change amount (dAx, dAy) is limited to 10. For the "upside-down position", with reference to Figure 26, 2 times an output value (INx, INy) of the XY-axis acceleration sensor 31 gives an X-and-Y moving-acceleration change amount (dAx, dAy) (moving amount greater because the tortoise "backside-down" easily slide as compared to "normal"). Also, where the output value (INx, INy) of the XY-axis acceleration sensor 31 is greater than 20 under special correction condition 1, the moving-acceleration change amount (dAx, dAy) is limited to 40.

[0049]

In the NPC moving tables, the output value (INz) of the Z-axis contact switch 32 is utilized to determine tortoise inversion to a normal or inverted position. Each time the output value of contact switch 32 becomes "1", the tortoise turns to a normal or inverted state in a repetitive manner. The impact input flag (FS) is not utilized for the NPC movement process.

[0050]

Figure 27 is a flowchart of a main routine. If a cartridge 30 is loaded onto the game machine main body 10 and the power switch of the game machine main body 10 is turned on, the CPU 21 starts to process the main routine of Figure 33. First, in step 11 it is determined whether it is a first starting or not, or whether a player requested for OG setting (e.g. whether started while pressing the operation key 13b of Figure 1) or not. If not a first starting and there was no OG set request, the process advances to step 13. Meanwhile, when a first starting or there was a OG set request, a OG set process hereinafter described with reference to Figure 28 is made in step 12 and then the process proceeds to step 14. In the step 14, a neutral-position set process hereinafter described with reference to Figure 29 is made and then the process advances to step 17. Here, the neutral-position setting is meant to set a reference tilt of the game apparatus for playing a game. The recommended position setting is meant to set a neutral position based on data wherein the data is concerned with a proper neutral position in accordance with a game content (the recommended position sight target coordinate 34d of the program ROM 34) that have been previously memorized in a game program.

[0051]

In step 17 a game map select process hereinafter described with reference to Figure 30 is performed so that one of a plurality of game maps is selected by the player.

After the step 17, the process advances to a main loop.

[0052]

The main loop is a process of from step 19 to step 29, which is repeatedly executed until game over or game clear is reached. In step 19, required data is written to the display RAM 25 based on a coordinate (X, Y, Z) and pose number (PN) of the character data 26g of the work RAM 26, object character data 34a of the program ROM 34 and map data 34b. Based on the data stored in the display RAM, a game scene is displayed on the LCD 12. In step 20 a sensor output read process hereinafter described with reference to Figure 31 is performed. The output values of the XY-axis acceleration sensor 31 and Z-axis contact switch 32 are read out through the sensor interface 33 and then corrected. After the step 20, in step 21 it is determined whether there was a neutral-position set request or not. If there was no request, the process advances to step 23 while if there was a request the process proceeds to step 22 to perform a neutral-position set process. After resetting a neutral position, the process returns to step 19. This means that one operation switch (e.g. operation switch 13e shown in Figure 1) is assigned to an exclusive operation switch for neutral-position setting so that neutral-position setting can be made at any time by pressing the operation switch 13e even during playing a game.

[0053]

In step 23 it is determined whether the impact input flag is ON or not. If the impact input flag is OFF, the process proceeds to step 26 while if ON the process advances to step 24 to determine whether the topology of current coordinate that the player character is present is under-water or not (determined based on a current position status). If not under-water is determined, the process advances to step 26 while if determined under-water, the process advances to step 25 to perform a wave producing process (display is as shown in the middle portion in Figure 15). Specifically, processing

is made to cause waves in a direction and with a magnitude depending on a resultant vector, wherein the resultant vector is given by a vector component in the X-axis direction taken of a sensor output value X (INx) and a vector component in the Y-axis direction is taken of a sensor output value Y (INy). The player can have a feeling as if the impact applied by him or her to the game apparatus was reflected in an environment (water) of the game space. After step 25, the process proceeds to step 26.

[0054]

In the step 26 an each-character moving process hereinafter described with reference to Figure 32 to Figure 35 is performed thereby performing a process of moving the player character and NPC. After the step 27, a collision process hereinafter described with reference to Figure 37 is performed thereby performing a process of colliding the player character with NPC, etc. After the step 27, a scroll process hereinafter described with reference to Figure 40 is performed.

[0055]

Figure 28 shows a subroutine flowchart for a 0G set process. This subroutine performs a process to store as 0G position data to backup RAM 35 an output value of the XY-axis acceleration sensor 31 when the game apparatus (specifically, the LCD 12 display surface) is held horizontal.

[0056]

In step 121 "POSITION HORIZONTAL TO GROUND AND PRESS OPERATION SWITCH" is displayed on the LCD 12, requesting the player to hold the game apparatus (specifically, the LCD 12 display surface) in a horizontal state. In step 122 an operation switch input process is performed. In step 123, if depression of an operation switch (e.g. operation switch 13b of Figure 1) for determination is determined, it is then determined in step 124 whether the Z-axis contact switch 32 is ON or not. When

the Z-axis contact switch 32 is ON, an alert sound is generated in step 125 and the process returns to step 121. This is because, where the Z-axis contact switch is ON, the LCD in its display surface is directed downward and the player is requested to perform setting again. In step 124, where the Z-axis contact switch is determined OFF, then in step 126 the output value of the XY-axis acceleration sensor 31 at this time is stored as 0G position data to the backup RAM 35.

[0057]

Figure 29 is a subroutine flowchart for a neutral-position set process. This subroutine performs process that the player arbitrarily determines a game apparatus at a holding angle easy to play a game. The output value of the XY-axis acceleration sensor 31 and Z-axis contact switch 32 at that time are stored as neutral position data to the work RAM 26.

[0058]

In step 141 "POSITION AT ANGLE EASY TO PLAY AND PRESS OPERATION SWITCH" is displayed on the LCD 12. In step 142 an operation switch input process is made. In step 143, if the depression of an operation switch for determination (e.g. operation switch 13b of Figure 1) is determined, then in step 144 correction is performed by subtracting 0G position data from an output value of the XY-axis acceleration sensor 31 at this time (the neutral position data is rendered as data corresponding to a tilt with respect to the horizontal state). Then, in step 145 a correction value of the output of the XY-axis acceleration sensor (calculation result of step 144) and an output value of the Z-axis contact switch 32 are stored as neutral position data to the neutral position data memory area 26a of the work RAM 26.

[0059]

Figure 30 is a flowchart of a game map select process. In this subroutine, the

player selects any one of a plurality of game maps stored in the game program. The screen of game map select process is displayed, for example, as shown in Figure 13 mentioned before. On the LCD 12, one area of a game-map select map is displayed. The player makes slide input in the X-axis or Y-axis direction to move the display area on the LCD 12 thereby displaying map icons (A, B, C, D in Figure 16) within the display area. Then, a movement is inputted in the Z-axis direction. This results in selection of a game course corresponding to a course icon being displayed on the LCD 12 upon inputting the movement (or impact) in the Z-axis direction.

[0060]

First, in step 171 a camera coordinate (C_x , C_y) is initialized. Then, in step 172 one area of the game-map select map is displayed on the LCD 12 based on the camera coordinate (C_x , C_y). In step 173 a sensor output read process hereinafter described with referring to Figure 31 is made. As a result, the output values of the XY-axis acceleration sensor 31 and Y-axis contact switch 32 are read out and corrected. In step 174 a table shown in Figure 26 is referred to. Specifically, the camera coordinate (C_x , C_y) is changed based on the sensor output values (IN_x , IN_y). Specifically, because the correction ratio is twice, the camera coordinate (C_x , C_y) is varied by an amount twice the sensor output value (IN_x , IN_y). For example, when the sensor output value (IN_x) is 5, the camera coordinate (C_x) is rendered +10. In step 175 it is determined whether the display area based on the camera ordinate (C_x , C_y) is outside a range of the game map select map or not. If not outside the range, the process advances to step 177 while if in outside the range the process proceeds to step 176. In step 176 correction is made so as to display an end area of the game-map select map and then the process proceeds to step 177. In the step 177 it is determined whether the Z-axis contact switch 32 is ON or not. If the contact switch 32 is determined OFF, the process returns to step 172. If the Z-axis contact switch

32 is determined ON, then it is determined in step 178 whether any one of the map icons (A, B, C, D in Figure 16) is displayed in the display range of the LCD 12 or not. If it is determined that no map icon is displayed within the display area, then in step 179 an alert sound is generated and the process returned to step 172. If it is determined that a map icon is displayed within the display range, then in step 181 a corresponding game map number (MN) to the map icon being displayed is stored to the work RAM 26.

[0061]

Figure 31 is a flowchart for a sensor output read process. In this subroutine, the output values of the XY-axis acceleration sensor 31 and Z-axis contact switch 32 are read out and corrected. Specifically, from the data of the latch 334 and latch 335 of the sensor interface 33 are read output values (INx, INy) of the acceleration sensor and an output value (INz) of the Z-axis contact switch 32. Furthermore, a correction process is made based on OG position data and neutral position data.

[0062]

In step 201, data is read out of the latch 334 and latch 335. In step 202, acceleration-sensor output values (INx, INy) and Z-axis contact switch output value (INz) are read from the latch data, and stored to the acceleration-sensor output value memory area 26b of the work RAM 26. In step 203 it is determined whether there was an impact input or not. Specifically, it is determined whether equal to or greater than a given value a magnitude of a resultant vector having vector component in the X-axis direction taken of the acceleration sensor 31 output value X (INx) and a vector component in the Y-axis direction taken of the acceleration sensor 31 output value Y (INy). If determined equal to or greater than a given value, then in step 204 the impact input flag (FS) is set "ON" and the process advances to step 206. If the resultant vector magnitude is determined smaller than the given value, then in step 205 the impact input flag (FS) is set

"OFF" and the process advances to step 206. In step 202, processing is made to subtract the 0G position data memorized in the backup RAM 35 from the data of the acceleration-sensor output value memory area 26b. In step 207, the value further corrected with the neutral position data is stored as INx, INy and INz to the acceleration-sensor output memory area 26b.

[0063]

The correction with the neutral position data is performed, specifically, on the output value X (INx) and output value Y (INy) of the acceleration sensor by subtracting the values of the neutral position data (NPx, NPy). For the output value (INz) of the Z-axis contact switch 32, when the value of neutral position data (NPz) is "1", processing is made to invert "0" and "1".

[0064]

Figure 32 to Figure 36 are flowcharts for an object moving process. Figure 32 is an object moving process main routine flowchart. In step 261, a player-character moving process is performed that is hereinafter described with reference to Figure 33. In step 262, an NPC moving process is performed that is hereinafter described with reference to Figure 34. The NPC moving process is repeated the number of NPCs.

[0065]

Figure 33 is a player-character moving process flowchart. In step 31, a present coordinate (X, Y, Z) of the player character is stored by copy as a last-time coordinate (Px, Py, Pz). This is required to return the player character collided with a wall to a last-time coordinate, in a collision process hereinafter described with reference to Figure 37. In step 32, a moving-acceleration change amount (dAx, dAy, dAz) is initialized, and then in step 33 a tilt movement process is performed. In the tilt movement process, reference is made to proper one of the conversion tables shown in Figure 21 to Figure 24 depending

upon a present position status of the player character, to make processing of calculating an X-and-Y moving-acceleration change amount of the player character. This processing determines a moving-acceleration change amount (dAx , dAy) such that the character is rolled (slid) responsive to a tilt (tilt input) of the portable game apparatus. Furthermore, in step 34, an impact moving process is performed. In the impact moving process, reference is made to proper one of the conversion tables of Figure 21 to Figure 24, to make processing of increasing an X-and-Y change amount of the player character. This process increases a moving-acceleration change amount (dAx , dAy) such that the player character makes a dash (moves at higher speed) when applying an impact input. In step 35, a jump moving process is made that is hereinafter described with reference to Figure 35. After the step 35, it is determined in step 36 whether a wave generation process in step 25 of the flowchart of Figure 27 has been made or not. If no wave generation is determined, the process advances to step 38. If waves have generated is determined, in step 37 a wave moving process hereinafter described with reference to Figure 36 is made, and then the process proceeds to step 38. In the step 38, a moving acceleration (Ax , Ay , Az) is calculated based on the moving-acceleration change amount (dAx , dAy , dAz) calculated in the tilt moving process, impact moving process, jump process and wave moving process of the step 33 to 37, and a velocity (Vx , Vy , Vz) is calculated based on the moving acceleration (Ax , Ay , Az). In step 39, a coordinate (X , Y , Z) is calculated based on the velocity (Vx , Vy , Vz).

[0066]

Figure 34 is a flowchart of an NPC movement process. In step 41 a current coordinate (X , Y , Z) is stored by copy to the last-time coordinate (Px , Py , Pz). In step 42 the moving-acceleration change amount (dAx , dAy , dAz) are initialized. In step 43 an NPC self-controlled movement process is executed based on the game program.

Specifically, a moving-acceleration change amount (dAx , dAy , dAz) e.g. for a tortoise is determined based on a random number value. After the step 43, in step 44, a tilt movement process is executed. In the tilt movement process, processing is made to calculate an NPC X-and-Y moving-acceleration change amount by referring to a suited one of the conversion tables shown in Figure 25 or Figure 26 according to an NPC pose number. Furthermore, in step 45 an impact process is made. However, in the present embodiment, the NPC will not be affected by impact input. In step 46 it is determined whether a wave producing process has been made in step 25 of the flowchart of Figure 25 or not. If no wave production is determined, the process advances to step 48. If waves have been produced is determined, then in step 47 a wave movement process hereinafter described with reference to Figure 36 is executed and then the process advances to step 48. In step 48, a moving acceleration (Ax , Ay , Az) is calculated based on the moving-acceleration change amounts (dAx , dAy , dAz) determined by the self-controlled movement process, tilt movement process, impact movement process and wave movement process of step 43 to S47. Furthermore, a velocity (Vx , Vy , Vz) is calculated based on the movement acceleration (Ax , Ay , Az). In step 49 a coordinate position (X , Y , Z) is calculated based on the velocity (Vx , Vy , Vz). In step 51 it is determined whether an output value (INz) of the Z-axis contact switch is "1" or not. In the case that the Z-axis contact switch output value (INz) is "0", the NPC movement process subroutine is ended. Where the Z-axis contact switch output value (INz) is "1", an inversion process to a normal or upside-down position is executed in step 52. Specifically, a pose number (PN) of the character data in the work RAM 26 is changed.

[0067]

Figure 35 shows a flowchart of a jump process. In this subroutine, when there is a movement input in the Z-axis direction, processing is made to cause the player character

to jump. Also, when there is no movement input in the Z-axis direction in a state the player character is in the air, processing is made to descend the player character.

[0068]

In step 351 it is determined whether the output value (INz) of the Z-axis contact switch 32 is 1 or not. When the output value (INz) of contact switch 32 is "1", the current position status (PS) is set as "in-air" in step 52. Thereafter in step 353 the Z moving-acceleration change amount (dAz) is rendered "1". When the output value (INz) of the Z-axis contact switch 32 is "0" in the step 351, it is determined in step 354 whether the player character is "in-air" or not. When not "in-air", the jump process is ended. Where "in-air" in the step 354, the Z moving-acceleration change amount (dAz) is rendered "-1" in step 355 and then the jump process is ended.

[0069]

Figure 36 shows a flowchart of a wave movement process. In this subroutine, processing is made to calculate a moving-acceleration change amount due to the waves produced due to impact input by the player. In step 361 a current position status is read in. In step 362 it is determined whether the current position status is in a position to undergo an affection of waves or not (i.e. "under-water" or not). If determined as a position free from an affection of waves, the wave movement process is ended. If determined as a position to undergo an affection of waves, then in step 363 are calculated respective X and Y moving-acceleration change amounts due to an affection of waves and added to the X and Y moving-acceleration change amounts calculated by the tilt movement process and impact movement process.

[0070]

Figure 37 shows a flowchart of a collision process. In step 271 to 275, an NPC collision determination process is carried out. The NPC collision determination process

is repeated to the number of NPCs. In step 271 it is determined whether an NPC has collided with a wall or not. If determined as collision with a wall, the process proceeds to step 273. If no collision is determined, the process advances to step 272 wherein it is determined whether there has been a collision with another NPC or not. If determined as collision with another NPC, the process advances to step 272. If determined as no collision with another NPC, the process proceeds to step 273. Where determined as a collision with a wall or another NPC, then in step 273 an impact sound is generated and then in step 274 the NPC coordinate (X, Y, Z) is returned to the last-time coordinate (Px, Py, Pz), and the process advances to the step 275.

[0071]

In step 275, a current position status of NPC is detected and stored in the work RAM 26. After step 275 it is determined in step 276 whether the player character has collided with a wall or not. If no collision against wall is determined, the process proceeds to step 279. If a collision with a wall is determined, then in step 277 an impact sound is generated and then in step 278 the player character coordinate (X, Y, Z) is returned to the last-time coordinate (Px, Py, Pz), and the process advances to step 279.

In step 279, a current position status of the player character is detected and stored in the work RAM 26. After step 279, it is determined in step 281 whether the player character has collided with an NPC or not. If a collision against an NPC is determined, a process is made in step 282 to vanish the NPC. After step 282, it is determined in step 283 whether all the NPCs have been vanished or not. If all the NPCs have vanished is determined, a game clear process is executed in step 284. When no collision with an NPC is determined in step 281 or when all the NPCs have not vanished is determined in step 283, the process proceeds to step 285. In step 285 it is determined whether the player character has fallen in a hole or not. If determined fallen in a hole, a game over process is

effected in step 286. Where the determination is not fallen in a hole, the impact process is ended.

[0072]

Figure 38 and 39 each show one example of a scene showing on-screen scroll. In the scene, there are displayed a ball as a player character, tortoises 62a – 62c as NPC, and a wall 63 and hole 64 forming a maze. The dotted lines 65 show a limit of screen scroll (actually, the dotted lines 65 will not be displayed on the LCD 12). The game map is a virtual map that is broader than LCD 12 display area, as stated before. On the LCD 12 is displayed part of a game map around the player character 61. When the player tilts or so the portable game apparatus and the player character 61 is moving to an outer area of the dotted lines 65, the scene is scrolled moving the game-map display area over the LCD12. Furthermore, the player character 61 and NPC 62 are moved to and displayed in a position toward a center of a scene by a corresponding amount to scrolling. In this manner, screen scrolling makes possible game play with a broader game map.

[0073]

For example, if the player character is going beyond the dotted line 65 to a left side area as shown in Figure 38, the game map area in display is scrolled to left so that the player character 61 and NPC can be moved to and displayed in a position by a corresponding amount to scrolling (Figure 39). Note that the scroll rate may be changed depending upon a magnitude of tilt input.

[0074]

Figure 40 shows a flowchart of a screen scroll process. In step 291 it is determined whether the player character is out of a scroll area in an X-axis minus direction or not. Here, the scroll area refers to an area as surrounded by the dotted lines 65 shown in Figure 38. If determined not out of the area with respect to the X-axis minus direction, the

process advances to step 294. If determined out of the area in the X-axis minus direction, it is then determined in step 292 whether the current display area on the LCD 12 is a left end area of the game map or not. If determined as a left end area, the process advances to step 294. If determined not a left end area, then in step 293 a scroll counter X coordinate (SCx) stored in the display RAM 25 is decreased by a given amount and then the process proceeds to step 294. In step 294 it is determined whether the player character is out of the scroll area with respect to the X-axis plus direction or not. When determined not out of the area in the X-axis plus direction, the process advances to step 297. When determined out of the area in the X-axis plus direction, it is determined in step 295 whether the current display area on the LCD 12 is a right end area of the game map or not. If determined as a right end area, the process advances to step 297. When determined not a right end area, in step 296 the scroll counter X coordinate (SCx) is increased by a given amount and then the process proceeds to step 297.

[0075]

In step 297 it is determined whether the player character is out of the scroll area in a Y-axis minus direction or not. If determined not out of the area in the Y-axis minus direction, the process advances to step 301. When determined out of the area in the Y-axis minus direction, it is determined in step 298 whether the current display area on the LCD 12 is an upper end area of the game map or not. If determined as an upper end area, the process proceeds to step 301. When determined not an upper end area, in step 299 a scroll counter Y coordinate (SCy) is decreased by a given amount and then the process proceeds to step 301. In step 301 it is determined whether the player character is out of the scroll area in a Y-axis plus direction or not. When determined not out of the area in the Y-axis plus direction, the screen scroll process is ended. When determined out of the area in the Y-axis plus direction, it is determined in step 302 whether the current display

area on the LCD 12 is an lower end area of the game map. When determined as a lower end area, the screen scroll process is ended. When determined not a lower end area, in step 303 the scroll counter Y coordinate (SCy) is decreased by a given amount and then the screen scroll process is ended.

[0076]

(Second Embodiment)

Next, a game apparatus according to a second embodiment of the invention will be explained with reference to Figure 41 to Figure 49. The second-embodiment game apparatus is common in external view, XY-axis definition diagram, block diagram, sensor-interface measurement principle diagram and Z-axis contact switch structural view to Figure 1 to Figure 7 of the first embodiment, hence omitting explanations thereof.

[0077]

Figure 41 illustrates an example of a game scene in the present embodiment. In this game, a player can give impact to the game apparatus to cause an upheaval in a game-space land, enjoying the game while controlling the movement of a game character.

[0078]

As shown in Figure 41(a), a game-character tortoise 81 and a land-upheaval character 82 are displayed in a game scene. As shown in Figure 41(b), the tortoise 81 is moved self-controlled according to a game program. In a state shown in Figure 41(b), when an impact input is given in the Z-axis direction to the game apparatus, the land-upheaval character 82 is displayed higher and greater with upheaval, as shown in Figure 41(c). This controls the tortoise 81 to slide (tortoise 82 in advancing retracts due to land upheaval). By thus processing, it is possible to provide the player with a feeling as if the game-space land receives energy and is upheaved when an impact is applied in the Z-axis direction to the game apparatus.

[0079]

Figure 42 is one example of a game scene illustrating a land-upheaval process due to an impact input in the Z-axis direction. In Figure 42(a), an outer frame 12' designates a whole game space and an inner frame 12 a display area to be displayed on the LCD 12. The game space is a world greater than a display area of the LCD 12. The LCD 12 displays a part of the game space. In the game space, there are twelve land-upheaval characters 82 (82a - 82l) and three tortoise characters 81 (81a - 81c). Among them, four land-upheaval characters (82a, 82b, 82e, 82f) and one tortoise character (82a) are being displayed on the LCD 12.

[0080]

In a state shown in Figure 42(a), if an impact input is applied in the Z-axis direction to the game apparatus, the twelve land-upheaval characters (82a - 82l, the land-upheaval characters all over the game space) are raised by one step and displayed higher and greater, as shown in Fig. 42(b). At this time, the tortoise characters (81a and 81b) existing at land upheaval are displayed sliding due to the upheaval of land.

[0081]

In a state shown in Figure 42(b), when an impact input is applied in the Z-axis direction while operating the button A (operation switch 13b), only the four land-upheaval characters (82a, 82b, 82e, 82f) being displayed on the LCD 12 are further raised by one step and displayed higher and greater. In also this case, the tortoise character (81a) existing at land upheaval is displayed sliding due to the land upheaval. By thus processing, when applying an impact input in the Z-axis direction while pressing the button A, it is possible to provide the player with a feeling as if energy due to impact was given to the game space limited to the area being displayed on the LCD 12.

[0082]

Incidentally, although not shown, if in the state shown in Figure 42(b), an impact input is given in the Z-axis direction while operating the button B (operation switch 13c), only the eight land-upheaval characters (82c, 82d, 82g, 82h, 82i - 82l) not being displayed on the LCD 12 are raised by one step and displayed higher and greater. In also this case, the tortoise characters (81b, 81c) existing at the land upheaval are displayed sliding due to the land upheaval. By thus processing, where an impact input is given in the Z-axis direction while pressing the button B, it is possible to provide the player with a feeling as if energy due to impact was supplied to the game space limited to the area not being displayed on the LCD 12.

[0083]

Figure 43 is one example of a game scene illustrating a scroll process for a game space on display. The game space on display is to be scrolled by giving a slide-input to the game apparatus (see Figure 9 in the first embodiment). For example, in Figure 43(a) land-upheaval characters 82a, 82b, 82e, 82f and tortoise character 81a are displayed on the LCD 12. In this state, when the game apparatus is slid in a Y-axis minus direction, the game space on display is scrolled down, resulting in display of land characters 82e, 82f and tortoise character 81a as shown in Figure 43(b).

[0084]

Also, in a state shown in Figure 43(b), when the game apparatus is slid in an X-axis plus direction, the game space on display is scrolled right, to provide display with a land character 82f and tortoise character 81a. By thus processing, it is possible for the player to enjoy a game with a game space greater than the LCD 12. Also, because as stated before an effect (land upheaval) can be given to the game space limited to an inside or outside of the area of display by the use of the button A or button B, the player can enjoy a complicated game.

[0085]

Figure 44 illustrates control of scenes with temperature increase caused by impact input in XY-axis directions. Although the tortoise characters 81a - 81c moves in a self-controlled fashion according to the game program as stated before, this self-controlled movement becomes more active as temperature increases (specifically, moving amount increases). In a state shown in Figure 44(a), when an impact input is applied in the XY-axis direction (see Figure 11 in the first embodiment), a parameter of temperature increases to provides display that the tortoise characters 81a - 81c are actively moving. By thus processing, it is possible to provide the player with a feeling as if energy was supplied and the temperature was increased in the game space upon giving an impact in the XY-axis direction to the game apparatus.

[0086]

Hereunder, explanations will be made on the data stored on the memory with reference to Figure 45 and Figure 46.

Figure 45 is a memory map of the program ROM 34. The program ROM 34 stores a game program and game data to be executed by the CPU 21. The program ROM 34, concretely, includes an object-character data memory area 342a, a map-data memory area 342b, a land-upheaval-point data memory area 342c, a scroll-limit value data memory area 342d, an acceleration-sensor output value conversion table memory area 342e and a game program memory area 342f. The object-character data memory area 342a and the map-data memory area 342b store object characters and game-map graphic data. The land-upheaval-point data memory area 342c stores position data (X coordinate and Y coordinate; Px1 - Px12, Py1- Py12) in a game space for each of the land upheaval characters (82a - 82l) shown in Figure 42. The scroll-limit-value data memory area 342d stores data representative of scroll limit values (SCxmax, SCymax) in order not to make

scrolling at an up, down, left or right end of the game space when scrolling the game space.

[0087]

The acceleration-sensor output value conversion table memory area 342d stores a conversion table to convert, and utilize in a game program, output values of the XY-axis acceleration sensor 31 and Z-axis contact switch 32. Specifically, stored is data similar to that of the conversion tables (Figure 20 to Figure 26) of the first embodiment. It is defined that a sensor output value X (INx) and sensor output value Y (INy) is to be utilized in calculating a change amount of a scroll counter X coordinate (SCx) and Y coordinate (SCy) in a range-of-sight moving process hereinafter described with reference to Figure 48. Due to this, by giving a slide-input to the game apparatus (see Figure 9 in the first embodiment), the game space on display is scrolled thereby making processing to move the range of sight. Also, definition is made to utilize a Z-axis contact switch output value (INz) in land upheaval determination. Definition is made to utilize an impact input flag (FS) in temperature rise determination.

[0088]

The game program memory area 342f stores a game program to be executed by the CPU 21. Specifically, stored are a main program hereinafter described with reference to Figure 47, a sensor output read program similar to Figure 31 of the first embodiment, a range-of-sight moving program hereinafter described with reference to Figure 48, a land upheaval program hereinafter described with reference to Figure 49, a temperature raising program, a tortoise-character control program and other programs.

[0089]

Figure 46 is a memory map of the work RAM 26. The work RAM 26 stores temporary data for the CPU 21 to execute a game program. Specifically, included are an

acceleration-sensor output value memory area 162a, an impact input flag memory area 262b, a land-upheaval data memory area 262c, a temperature data memory area 262d and a character data memory area 262e.

[0090]

The data stored on the acceleration-sensor output value memory area 262a and impact input flag memory area 262b is similar to that of the first embodiment, hence omitting explanations. The land-upheaval data memory area 262c stores height data concerning respective points of land upheaval. The height data is varied according to an impact input in the Z-axis direction in a land upheaval process hereinafter described with reference to Figure 49. Based on this data, the land upheaval characters at respective land upheaval points are determined in state of display. For example, where the height data is 1, the land upheaval character is displayed as shown at 82a in Figure 42(a). Where the height data is 2, display is as shown at 82a in Figure 42(b). Where the height data is 3, display is as shown at 82a in Figure 42(c).

[0091]

The temperature data memory area stores temperature data for the game space. The temperature data is varied according to an impact input in the XY-axis direction, in a temperature increase process (in step 64 of the main program shown in Figure 47). This data has an effect upon a tortoise-character control process (self-control movement, in step 65 of the main program shown in Figure 47).

The character-data memory area 262e stores coordinate data (X, Y, Z) and last-time coordinate data (Px, Py, Pz), in the number of the tortoise characters.

The memory map of the display RAM is similar to that of Figure 18 of the first embodiment, hence omitting explanation.

[0092]

Hereunder, a process flow of a game program will be explained with reference to Figure 47 to Figure 49.

Figure 47 is a main routine flowchart. When a cartridge 30 is inserted to the game apparatus main body 10 and the power to the portable game apparatus main body 10 is turned on, a main routine as shown in Figure 47 is started. Although in also the second embodiment a 0G position process or neutral-position set process may be made similarly to the first embodiment, explanation is omitted herein for the sake of simplifying explanation.

[0093]

First, in step 61 a sensor output read process is carried out similarly to Figure 31 of the first embodiment. This reads output values of the XY-axis acceleration sensor 31 and Z-axis contact switch 32 through the sensor interface 33 (corrections by 0G position data and neutral position data is omitted). After the step 61, in step 62 a range-of-sight moving process (scroll process of a game space on display) is made that is hereinafter described with reference to Figure 48. After the step 62, in step 63 a land upheaval process is made that is hereinafter described with reference to Figure 49. After the step 63, in step 64 a temperature increase process is made. In the temperature increase process, it is first determined whether there is an impact input in the XY-axis direction or not. In the case of the presence of an impact input in the XY-axis direction, processing is made to increase a temperature parameter (T) by 1. After the step 64, in step 65 a tortoise-character control process is made. In the tortoise-character control process, a tortoise-character moving process is first made due to self-controlled movement. Specifically, processing is made to calculate a tortoise-character moving amount, e.g. using random values. Incidentally, control is made such that the self-controlled movement of a tortoise character increases in amount as the temperature (T) is higher. Thereafter, a tortoise-character moving process

is made with land upheaval. Specifically, processing is made to move the tortoise character sliding when a land under the tortoise character is raised. Incidentally, the tortoise-character control process is repeated the number of the tortoise characters.

[0094]

After the step 65, in step 66 game-space scrolling as well as display process for a land upheaval object and tortoise character are made based on a result of the range-of-sight moving process, land-upheaval process and tortoise-character control process. Incidentally, where a land upheaval point is raised in height due to the land upheaval process, it would be effective to display the land upheaval character higher and greater together with generation of such sound as imagining an upheaval of a land. After the step 66, it is determined in step 67 whether game is over or not. For example, game-over determination is to be made under a proper condition suited for a game content, including effecting game over, e.g. when a predetermined time has elapsed. If game over is determined in the step 67, the main routine is ended. If no game over is determined in the step 67, the process returns to the step 61.

[0095]

Figure 48 is a range-of-sight moving process flowchart. First, in step 621 reference is made to conversion table, to perform a process of changing a scroll-counter X coordinate (SCx) and Y coordinate (SCy). After the step 621, it is determined in step 622 - 629 whether scroll is about to exceed an end of the game space or not. When scroll is about to exceed a game-space end, processing is made to bring the scroll counter value (SCx, SCy) to a proper value.

[0096]

In step 622, it is determined whether the scroll-counter X coordinate (SCx) is in excess of a scroll limit value X coordinate (SCxmax) or not. If not in excess of it, the

process advances to step 624. When in excess of that is determined in step 622, the process proceeds to step 623. After setting the scroll-counter X coordinate (SCx) value to the scroll limit value X coordinate (SCxmax), the process advances to step 624.

[0097]

In step 624, it is determined whether the scroll-counter X coordinate (SCx) is smaller than 0 or not. If determined 0 or greater, the process advances to step 626. Where determined smaller than 0 in the step 624, the process proceeds to step 625 to set the scroll-counter X coordinate (SCx) value at 0, and then the process proceeds to step 626.

[0098]

In step 626, it is determined whether the scroll-counter Y coordinate (SCy) is in excess of the scroll-limit-value Y coordinate (SCymax) or not. If determined not in excess thereof, the process proceeds to step 628. Where determined in excess thereof in the step 626, the process advances to step 627 to set a Y coordinate (SCy) value to the scroll-limit-value Y coordinate (SCymax), and then the process advances to step 628.

[0099]

In the step 628, it is determined whether the scroll-counter Y coordinate (SCy) is smaller than 0 or not. If determined 0 or greater, the range-of-sight moving process is ended. If determined smaller than 0 in the step 628, the process proceeds to step 629 to set the scroll-counter Y coordinate (SCy) value at 0, and then the range-of-sight moving process is ended.

[0100]

Figure 49 is a land-upheaval process flowchart. First, it is determined in step 631 whether there is an output of the Z-axis contact switch or not (i.e. whether there is an impact input in the Z-axis direction or not). Where determined as an absence of a Z-axis contact switch output, the land-upheaval process is ended. Where determined as a

presence of a Z-axis contact switch output, the process advances to step 632. In the step 632, it is determined whether the button A (operation switch 13b) is being pressed or not. Where determined that the button A being pressed, the process advances to step 633 to make processing of increasing by 1 the respective land-upheaval points in an area being displayed on the LCD. After the step 633, the land-upheaval process is ended.

[0101]

If it is determined in the step 632 that the button A is not being pressed, the process proceeds to step 634 to determine whether the button B (operation switch 13c) is being pressed or not. If determined that the button B is being pressed, the process proceeds to step 635 to make processing of increasing by 1 the height (H) of the land upheaval points outside the area being displayed on the LCD. After the step 635, the land upheaval process is ended. If it is determined in the step 634 that the button B is not being depressed, in step 636 all the land upheaval points in height (H) are increased by 1, and then the land upheaval process is ended.

[0102]

(Third Embodiment)

Next, a third embodiment of the invention will be explained with reference to Figure 50 to Figure 59. This game is to enjoy virtual cooking while moving the game apparatus as if it was a frypan or kitchen knife.

[0103]

Figure 50 to Figure 53 shows examples of game scenes. In Figure 50, in the game scene are displayed a player character 91, a kitchen 92, a cooking stove 93, a frypan 94, a desk 95 and a chopping board 96. When pressing the button A (operation switch 13b), a frypan space process is started that is hereinafter described with reference to Figure 51 and Figure 52. Also, when pressing the button B (operation switch 13c), a kitchen-knife

space process is started that is hereinafter described with reference to Figure 53.

[0104]

Figure 51 and Figure 52 are examples of game scenes in the frypan space process. In the frypan space process, the game apparatus is operated just like a frypan to play a game of cooking a fried egg. In Figure 51(a), a frypan 94 and egg 97 is displayed in the game scene. In a state shown in Figure 51(a), when the portable game apparatus is tilted in a minus direction about the Y-axis, the egg 97 is displayed moving toward left of the frypan as shown in Figure 51(b). Also, in a state shown in Figure 51(b), when the portable game apparatus is tilted in the plus direction about the X-axis, the egg 97 is displayed moving toward the down of the frypan. By thus processing, it is possible to provide the player with a feeling as if he or she operates the game apparatus just like a frypan to move an egg by the tilt of the frypan.

[0105]

In a state shown in Figure 52(a), when an impact input in the Z-axis direction is applied to the game apparatus, the egg 97 is displayed jumping above the frypan 94 as shown in Figure 52(b). Thereafter, the egg 97 is displayed landing as shown in Figure 52(c) or (d). At this time, where the egg 97 at an impact input in the Z-axis direction is positioned close to an end of the frypan 94 as shown in Figure 52(a), the egg 97 jumps and lands out of the frypan 94 (Figure 52(c)) thus resulting in failure. Incidentally, in a state shown in Figure 52(b), it is possible to modify a relative positional relationship between the egg 97 and the frypan 94 to land the egg 97 in the frypan 94 by sliding the portable game apparatus (Figure 52(d)). By thus processing, it is possible to provide the player with a feeling as if the game apparatus was operated just like a frypan to receive the jumped egg by the frypan.

[0106]

Figure 53 is examples of game scenes in a kitchen-knife space process. In the kitchen-knife space process, the game apparatus is operated just like a kitchen knife to play a game of cutting a cabbage into fine strips. In Figure 53(a), a kitchen knife 98 and cabbage 99 is displayed in the game scene. In the a shown in Figure 53(a), when the portable game apparatus is slid in the plus direction of the X-axis, the cabbage 99 is displayed moving left relative to the kitchen knife 98 as shown in Figure 53(b) (because the kitchen knife 98 is always displayed at a center of the game scene, the cabbage 99 is displayed moving relatively left). By thus processing, it is possible to operate the game apparatus as it was a kitchen knife and provide the player with a feeling as if he or she adjusts a position to cut the cabbage by controlling the positional relationship between the cabbage and the kitchen knife.

[0107]

Furthermore, in the state shown in Figure 53(b), when the game apparatus is vertically moved (movement input in the Z-axis direction), the cabbage 99 is displayed being cut by the kitchen knife 98 into fine strips. On this occasion, it will be more effective if generating sound of cutting the cabbage.

[0108]

Hereunder, explanation will be made on the data stored on the memory with reference to Figure 54. Incidentally, the program ROM 34 stores a program almost similar to the program ROM of the first embodiment (Figure 16). However, the acceleration-sensor output value conversion table memory area stores a table for a frypan, a table for jumping an egg and a table for a kitchen knife. The game program memory area stores main program, a sensor output read program, a frypan space program, an egg jump program, a kitchen knife space program and other programs. Incidentally, the frypan table in the acceleration-sensor output value conversion table will be referred to a

frypan space program hereinafter described with reference to Figure 56. The egg-jumping table will be referred to in an egg-jumping program hereinafter described with reference to Figure 58. The kitchen-knife table will be referred to in a kitchen-knife space program hereinafter described with reference to Figure 57.

[0109]

In the frypan table, the output value (INx, INy) of the XY-axis acceleration sensor 31 is defined to be utilized in calculating a change amount of an egg X-and-Y coordinate (Ex, Ey). Due to this, the display position of an egg is varied when a tilt is input to the game apparatus (see Figure 10 in the first embodiment), thereby displaying and controlling the egg as if it slides over the frypan. Also, the output value (INz) of the coordinate Z-axis contact switch 32 is to be utilized in jump determination of an egg. The impact input flag (FS) is defined not to be utilized.

[0110]

In the egg jumping table, the output value (INx, INy) of the XY-axis acceleration sensor 31 is defined to be utilized in calculating a change amount of an egg X-and-Y coordinate (Ex, Ey). Due to this, the display position of an egg is varied when inputting a slide to the game apparatus while the egg is in jump (see Figure 9 in the first embodiment). This provides display and control as if the relative position of the frypan and the egg was varied. Incidentally, in the egg jumping table, the correction ratio is defined a minus value. This is because in the present embodiment the frypan is displayed fixedly in the game scene and the egg is displayed moving relative to the frypan. Consequently, there is a need to display a movement of the egg in a direction reverse to the slide direction of the game apparatus. Also, the output value (INz) of the Z-axis contact switch 32 and the impact input flag (FS) are not utilized.

[0111]

In the kitchen-knife table, the output value (INx, INy) of the XY-axis acceleration sensor 31 is defined to be utilized in calculating a change amount of a cabbage X-and-Y coordinate (CAx, CAy). Due to this, when a slide is input to the game apparatus, the display position of the cabbage is varied to provide display and control as if the relative position of the cabbage and the kitchen knife were varied. Incidentally, in the kitchen-knife table, the correction ratio is defined minus value similarly to the egg-jumping table. This is because, in the present embodiment, the kitchen knife is fixedly displayed in the game scene. In order to display the cabbage moving relative to the kitchen knife, there is a need to display the cabbage moving in a direction reverse to a slide direction of the portable game apparatus. Also, the output value (INz) of the Z-axis contact switch 32 is utilized in determination in the cabbage cutting process, and the impact input flag (FS) is defined not to be utilized.

[0112]

Figure 54 is a memory map of the work RAM 26. The work RAM 26 stores temporary data to be used upon executing the game program by the CPU 21. Specifically, included are an acceleration-sensor output value memory area 263a, an impact input flag memory area 263b, an egg data memory area 263c and a cabbage data memory area 263d.

[0113]

The data stored in the acceleration-sensor output value memory area 263a and impact input flag memory area 263b is similar to the first embodiment, omitting explanation.

The egg data memory area 263c stores data of egg X coordinate (Ex), Y coordinate (Ey), height (Eh) and broiling conditions (Ef). The cabbage data memory area 263d stores data of cabbage X coordinate (CAx), Y coordinate (CAy) and cut conditions (CAc).

The memory map of the display RAM is similar to Figure 18 in the first embodiment, omitting explanation.

[0114]

Hereunder, a flow of game program process will be explained with reference to Figure 55 to Figure 59.

Figure 55 is a main routing flowchart. When a cartridge 30 is inserted in the game apparatus main body 10 and the power to the portable game apparatus main body 10 is turned on, a main routine shown in Figure 55 is started. Although in the third embodiment, 0G position set process or neutral-position set process may be made as in the first embodiment, it is omitted for the sake of simplifying explanation.

[0115]

First, in step 71 a sensor output read process is performed similarly to Figure 31 of the first embodiment to read an output value of the XY-axis acceleration sensor 31 and Z-axis contact switch 32 through the sensor interface 33 (correction by 0G position data and neutral position data is omitted). After the step 71, it is determined in step 72 whether the button A (operation switch 13b) is pressed or not. If in the step 72 the button A is pressed is determined, the process advances to step 73 to make reference to Figure 57 and perform a kitchen knife space process hereinafter described, then the process proceeds to step 76.

[0116]

If in the step 72, the button A is not pressed is determined, the process proceeds to step 74 to determine whether the button B (operation switch 13c) is pressed or not. If the B button is not pressed is determined in the step 74, the process advances to step 76. If the button B is pressed is determined in the step 74, the process advances to step 75 to perform a frypan space process hereinafter described with reference to Figure 56, then the

process advances to step 76.

[0117]

It is determined in the step 76 whether the game is over is not. Specifically, game over determination is made under a proper condition as suited to a game content, such as game over when a predetermined time has elapsed. If no game over is determined in the step 76, the process returns to the step 71. If game over is determined in the step 76, the main routine is ended.

[0118]

Figure 56 is a frypan space process flowchart. First, in step 771 reference is made to the frypan table to make a change process to the egg X coordinate (Ex) and Y coordinate (Ey). After the step 771, in step 772 an egg jump process is made that is hereinafter described with reference to Figure 58. After the step 772, in step 773 processing is made to increase the egg-broil condition (Ef) by 1. After the step 773, it is determined in step 774 whether the egg-broil condition (Ef) becomes 100 or greater or not. If it is determined that the egg-broil condition (Ef) is smaller than 100, the frypan space process is ended. If the egg-broil condition (Ef) is 100 or greater is determined, the process advances to step 775 to perform an egg success process. In the egg success process, a scene, e.g., of completing egg cooking is displayed and score-adding process is made. After the step 775, the frypan space process is ended.

[0119]

Figure 57 is a kitchen-knife space process flowchart. First, in step 741 reference is made to the kitchen-knife table to perform a change process to the cabbage X coordinate (CAx) and cabbage Y coordinate (CAy). After the step 741, in step 742 a cabbage cut process is made that is hereinafter described with reference to Figure 59. After the step 742, it is determined in step 743 whether the cabbage cut ratio (CAc) becomes 100 or

greater or not. If the cabbage cut ratio (CAc) is smaller than 100 is determined, the kitchen-knife space process is ended. If the cabbage cut ratio (CAc) is 100 or greater is determined, the process proceeds to step 774 to perform a cabbage success process. In the cabbage success process, a scene, e.g. of completing cabbage cutting is displayed and score-adding process is made. After the step 774, the kitchen-knife space process is ended.

[0120]

Figure 58 is an egg jump process flowchart. First, it is determined in step 772a whether there is an output of the Z-axis contact switch or not (e.g. whether there is an impact input in the Z-axis direction or not). If it is determined in the step 772a that there is no output of the Z-axis contact switch, the egg jump process is ended. If there is an output of the Z-axis contact switch is determined in the step 772a, in step 772b display is made jumping the egg. After the step 772b, in step 772c the egg is set in height (Eh) to CH (predetermined value). After the step 772c, in step 772d a sensor output read process is made similarly to Figure 31 of the first embodiment, thereby reading an output of the XY-axis acceleration sensor 31 and Z-axis contact switch 32 through the sensor interface 33 (correction by OG position data and neutral position data is omitted). After the step 772d, in step 772e reference is made to the egg jump table to perform a change process to the egg X coordinate (Ex) and egg Y coordinate (Ey). The step 772e, in step 772f processing is made to decrease the egg height (Eh) by 1. After the step 772f, in step 772g processing is made to display based on the egg X coordinate (Ex), Y coordinate (Ey) and height (Eh). After the step 772g, it is determined in step 772h whether the egg has landed or not, i.e. the egg height (Eh) has become 0 or not. If the egg has not landed is determined in the step 772h, the process returns to the step 772d. If the egg has landed is determined in the step 772h, it is determined in step 772a whether an egg landing position

is within the frypan or not. If determined within the frypan, then in step 772j a jump success process has made and then the egg jump process is ended. In the jump success process, for example, music of success is generated while displaying "SUCCESS" and score-adding process is made. Where it is determined in the S772I that the egg landing position is outside the frypan, in step 772k a jump failure process is made and then the egg jump process is ended. In the jump failure process, for example, music of failure is generated while displaying "FAILURE" and processing is made to render the egg-broil condition (Ef) 0 (re-frying egg cooking).

[0121]

Figure 59 is a cabbage cut process flowchart. First, it is determined in step 742a whether there is an output of the Z-axis contact switch or not (i.e. whether there is a movement input in the Z-axis direction or not). If there is no output of the Z-axis contact switch is determined in step 742a, the cabbage cut process is ended. If there is an output of the Z-axis contact switch is determined in the step 742a, it is determined in step 742b whether there is a cabbage below the kitchen knife or not. If it is determined in the step 742b that there is no cabbage below the kitchen knife, the cabbage cut process is ended. If there is a cabbage below the kitchen knife is determined in the step 742b, in step 742c a display process is made (display of cutting a constant amount of cabbage). After the step 742c in step 742d processing is made to increase the cabbage cut ratio (CAc) by 1 and then the cabbage cut process is ended.

[0122]

(Fourth Embodiment)

Next, a fourth embodiment of the invention will be explained with reference to Figure 60 to Figure 66. Figure 60 illustrates a concept view of a game space and example of a game scene of a plurality of game apparatuses. This game shares a game space

through communication between the game apparatuses so that a plurality of players can enjoy a game while competing (or cooperating) a game similar to the first embodiment. The game space has a maze plate that is common to the game apparatuses 10 and 40 so that the game images on the game apparatus 10 and game apparatus 40 are on the basis of the same game space data (note that the range of sight is different between the game apparatuses). On the LCD of the first game apparatus 10 a range 12 shown by the one-dot chain line is displayed. On the LCD of the second game apparatus 40, a range 42 shown by the dotted line is displayed. Similarly to the first embodiment, the tilt of the maze plate as a game space is simulated in accordance with a tilt of the game apparatus. However, in the present embodiment, simulation of a maze plate tilt is made by a value combining a tilt of the game apparatus 10 and a tilt of the game apparatus 40 (simulation of a maze plate tilt may be by a tilt of one game apparatus). A player on the game apparatus 10 would try to operate the tilt of the maze plate by tilting the game apparatus 10 in order to manipulate his or her own ball 61a. On the other hand, a player on the game apparatus 40 would try to operate the tilt of the maze plate by tilting the game apparatus 40 in order to manipulate his or her own ball 61b. Thus, they are difficult to tilt the maze plate in line with their intentions, providing enjoy for a more complicated game. Incidentally, in this embodiment, a communication cable 50 is used to communicate between the two portable game apparatuses. However, communication means such as wireless or portable phone may be utilized.

[0123]

The program ROM of the fourth embodiment stores data almost similar to that of the program ROM (Figure 16) of the first embodiment. However, further stored in a game program memory area a map confirming program hereinafter described with reference to Figure 63 and Figure 64 and a communication interrupt program hereinafter

described with reference to Figure 65 and Figure 66, in addition to those of the first embodiment.

[0124]

Among the programs stored in the game program memory area, the main program, the map confirming program and the communication interrupting program are different between the game apparatus 10 and the game apparatus 40. This is because to perform communication processing using the game apparatus 10 as a master unit and the game apparatus 40 as a slave unit, the detail of which will be hereinafter described with reference to Figure 61 to Figure 66.

[0125]

The work RAM of the fourth embodiment stores data almost similar to that of the work RAM 17 of the first embodiment. However, a composite data memory area is further included in addition to those of the first embodiment. The composite data memory area stores a composite value of an output value of the XY-axis acceleration sensor 31 and Z-axis contact switch 32 of the game apparatus 10 and an output value of the XY-axis acceleration sensor 31 and Z-axis contact switch 32 of the game apparatus 40.

The memory maps of the display RAM and backup RAM are similar to those of Figure 18 and Figure 19 of the first embodiment, omitting explanation.

[0126]

Hereunder, a flow of a game program process will be explained with reference to Figure 61 to Figure 66.

Figure 61 is a main routine flowchart to be executed in the game apparatus 10. Although in this embodiment the 0G set process, neutral-position set process and impact-input wave generation process are omitted for the sake of simplifying explanation,

these processes may be added similarly to the first embodiment.

[0127]

First, in step 81p a game-map select process is performed similarly to Figure 30 of the first embodiment. After the step 81p, in step 82p reference is made to Figure 63 to perform a master-machine-map confirming process hereinafter described with reference to Figure 63. After the step 82p, the process advances to step 83p.

[0128]

Step 83p to 85p are a main loop to be repeatedly processed until game-over or game-clear is reached. In step 83p, required data is written to the display RAM 25 based on the data of the work RAM 26 so that game scenes are displayed on the LCD 12 based on the data stored on the display RAM 25. In step 84p, an each-object moving process (wave moving process is omitted) is made similarly to that of Figure 32 to Figure 36 of the first embodiment, thus processing to move the player character and NPC. After the step 84p, in step 85p a collision process is performed similarly to that of Figure 37 of the first embodiment, thus processing to collide the player character with an NPC or the like. After the step 85p, in step 86p a screen scroll process is made similarly to that of Figure 40 of the first embodiment.

[0129]

Figure 62 is a main routine flowchart to be executed in the game apparatus 40. Although in this embodiment the OG set process, neutral-position set process and impact-input wave generation process are omitted in order for simplifying explanation, these processes may be added similarly to the first embodiment.

[0130]

First, in step 81c a game-map select process is made similarly to that of Figure 30 of the first embodiment. After the step 81c, in step 82c a slave-machine map confirming

process is performed that is hereinafter described with reference to Figure 64. After the step 82c, the process advances to step 83c.

[0131]

Step 83c to 88c are a main loop to be repeated until game-over or game-clear is reached. First, in step 83c required data is written to the display RAM 25 on the basis of the data of the work RAM 26 so that game scenes are displayed on the LCD 12 on the basis of the data stored on the display RAM 25. After the step 83c, in step 84c a sensor output read process is made similarly to that of Figure 31 of the first embodiment. This reads an output value of the XY-axis acceleration sensor 31 and Z-axis contact switch 32 through the sensor interface 33 (correction by 0G position data and neutral position data is omitted). After the step 84c, in step 85c an interrupt signal and the acceleration-sensor output value data (INx, INy, INz) read out in the former step 84 and stored to the work RAM 26 are transmitted to the game apparatus 10. The portable game apparatus 10 receives the interrupt signal and starts a master-machine communication interrupt process hereinafter described with reference to Figure 65. After the step 85c, in step 86c an each-object moving process (wave moving process is omitted) is performed similarly to that of Figure 32 to Figure 36 of the first embodiment, thereby performing a moving process for the player character and NPC. After the step 86c, in step 87c a collision process is performed similarly to that of Figure 37 of the first embodiment, thus processing to collide the player character with an NPC or the like. After the step 87c, in step 88c a screen scroll process is made similarly to that of Figure 40 of the first embodiment.

[0132]

Figure 63 is a master-machine map confirmation process flowchart to be executed in the game apparatus 10. First, in step 87p1 the map number data stored on ones own

work RAM 26 is transmitted to the game apparatus 40. After the step 87p1, in step 87p2 data transmission and reception is made. Specifically, received is the map number data transmitted from the portable game apparatus 40 in a step 87c3 of a slave-machine map confirmation process hereinafter described with reference to Figure 64. If data reception is determined in step 87p3, it is then determined in step 87p4 whether the own map number data agrees with the map number data of the portable game apparatus 40 received in the former step 87p2 or not. If agreement of the map number data is determined in step 87p4, the master-machine map confirmation process is ended. If no agreement of the map number data is determined in the step 87p4, the process returns to the game map select process in step 81p of the main routine of Figure 61.

[0133]

Figure 64 is a slave-machine map confirmation process flowchart to be executed in a game apparatus 40. First, in step 87c1 data transmission and reception is made. Specifically, received is the map number data transmitted from the portable game apparatus 10 in step 87p1 of the master-machine map confirmation process of Figure 63. If data reception is determined in step 87c2, in step 87c3 the map number data stored on ones own work RAM 26 is transmitted to the game apparatus 10. After the step 87c3, it is determined in step 87c4 whether the own map number data agrees with the map number data of the game apparatus 10 received in the former step 87c1 or not. If agreement of the map number data is determined in step 87c4, the slave-machine map confirmation process is ended. If no agreement of the map number data is determined in the step 87c4, the process returns to the game map select process in step 81c of the main routine of Figure 62.

[0134]

Figure 65 is a master-machine communication interrupt process flowchart to be

executed in the game apparatus 10. This process is started by an interrupt signal transmitted in the step 85c of the main routine for the portable game apparatus 40 shown in Figure 62. First, in step 91p data transmission and reception is made. Specifically, received is an acceleration-sensor output value of the game apparatus 40 transmitted in the step 85c of the main routine for the game apparatus 40 shown in Figure 62. After the step 91p, in step 92p a sensor output read process is made similarly to that of Figure 31 of the first embodiment, thereby reading an output value of the XY-axis acceleration sensor 31 and Z-axis contact switch 32 through the sensor interface 33 (correction by 0G position data and neutral position data is omitted). After step 92p, in step 93p composition is made of an acceleration-sensor output value of the game apparatus 40 received in the former step 91p and an acceleration-sensor output value of game apparatus 10 read out in the former step 92p. Here, composition may be by a calculation process of mere addition, or by calculation of a composite value from two values through a complicate calculation formula, e.g. adding two values together with weighting. After the step 93p, in step 94p an interrupt signal and the composite data calculated in the former step 93p are transmitted to the game apparatus 40.

[0135]

Figure 66 is a slave-machine communication interrupt flowchart to be executed in the game apparatus 40. This process is started according to an interrupt signal transmitted in step 94p of the master-machine communication interrupt process of Figure 65. In step 91c the composite data is received from the portable game apparatus 10, and the process is ended.

[0136]

Although in the above embodiment the portable game apparatus was provided with detecting means, detecting means may be provided on a controller of a home-use

game machine, personal computer, or business-purpose game machine as shown in Figure 67. In this case, a player can control a game space displayed on a display device, such as television receiver, by tilting or applying a movement or impact to the controller. For example, as shown in Figure 68 tilting the controller provides display of tilting a plate as a game space on the display device wherein simulation is provided to roll a ball on the plate. Simulation is such that tilting the controller to the right provides a tilt of the plate to the right to roll the ball to the right whereas tilting the controller to the left provides a tilt of the plate to the left to roll the ball to the left.

[0137]

Although in the above embodiments the acceleration sensor was provided on the cartridge, the acceleration sensor may be provided on the side of the portable game apparatus main body. In the case of providing an acceleration sensor on the side of the portable game apparatus main body, there is no need to provide an acceleration sensor for each cartridge, reducing cost. Also, the information storage medium used for the game apparatus is not limited to a cartridge but may be an IC card, such as a PC card.

[0138]

Although in the above first embodiment the neutral position data was stored on the work RAM 26 and set up each time of game play, it may be stored on the backup RAM 35 so that the same data can be utilized in next-round of game play.

[0139]

Although in the above first embodiment the neutral position was determined by a player, neutral position data may be previously stored in a game program so that it can be utilized. Also, a plurality of neutral position data may be stored so that a player can select any of them.

[0140]

In the first embodiment, the game characters employed only the player character (ball) and enemy character (tortoise). However, in addition to them, it is possible to appear NPC (non-player character), such as ally characters, assisting the player character or neutral characters. These NPCs, although self-controlled according to a game program (NPC not self-controlled may be provided), may be moved or deformed according to an operation (tilt, movement or impact input) by a player.

[0141]

Although in the above first embodiment game-space control was based only on an output of the acceleration sensor, there may provided a portion of a game space to be controlled according to an operation switch. For example, it is possible to contemplate such a game that in a pin ball game a flipper operates when pressing an operation switch while controlling a pin ball board as a game space by tilting or swinging the game apparatus. Also, in a game so-called "fall game" wherein fall objects are piled up so that score is calculated according to a state of piling up, it is possible to contemplate such a game that an object is changed in direction by operation switches or moved at high speed due to impact input or deformed due to movement input in the Z-axis direction while controlling the game space by tilting or swinging the game apparatus

[0142]

Although in the above first embodiment the game characters were moved in accordance with a tilt of the game apparatus (i.e. tilt of the maze plate as a game space), they may be moved according to a movement or impact to the game apparatus. For example, it is possible to contemplate to provide display and control such that, when the game apparatus is slid, simulation is given to move a maze plate wall similarly, moving a game character contacting the wall as if it were pressed by the wall.

[0143]

Although in the above embodiment the player character (ball) itself was displayed moving, the player character may be displayed fixedly and the game space be scrolled so that the player character is displayed moving relative to the game space.

[0144]

Although in the above fourth embodiment the two players made the same control to tilt the maze plate, the two players may do individual control. For example, it is possible to contemplate such a game that one player tilts the game apparatus to control and tilt a maze plate whereas the other player inputs movement in the Z-axis direction to the game apparatus to cause a game character to jump or applies an impact in the XY-axis direction to generate and control waves.

[0145]

In the above fourth embodiment, the portable game apparatus 10 stored the master-machine program and the portable game apparatus 40 a slave-machine program, in respect of the main, map confirmation and communication interrupt programs. Instead, both master-machine program and slave-machine program may be stored on each of the game apparatus 10 and the game apparatus 40 so that setting can be made as to which one is used as a master or slave unit prior to a start of a game and the program be selected according to such setting.

[Document name] ABSTRACT

[Abstract]

[Problem]

A game system and game information storage medium is provided that is used for same which can change the state of a game space through simple operation so that a player can concentrate on game play with enhanced enthusiasm without the necessity of skill on operation way.

[Solving means]

Change state detecting means is provided in a housing to be held by a player. The change-state detecting means detects at least one of an amount (e.g. tilt amount, movement amount, impact amount or the like) and a direction (e.g. tilt direction, movement direction, impact direction or the like) of a change applied to the housing. A simulation program simulates based on an output of the change-state detecting means such that a state of the game space is changed related to at least one of a change amount and a change direction applied to the housing.
